Natural Language Understanding with Distributed Representations - Assignment 1

In this assignment, you will extend the ConvNet you have implemented during the lab session. In particular, you will change the activation function, implement a new regularizer and use deeper models.

In the skeleton code we provide an implementation for a model similar to Kim Yoon's Convolutional Neural Networks for Sentence Classification [1]. The model presented in the paper achieves good classification performance across a range of text classification tasks (like Sentiment Analysis) and has since become a standard baseline for new text classification architectures.

The dataset we use in this assignment is the Movie Review data from Rotten Tomatoes, one of the datasets also used in the original paper. The dataset contains 10,662 example review sentences, half positive and half negative. The dataset has a vocabulary of size around 20k. Note that since this dataset is pretty small we are likely to overfit with a powerful model. Also, the dataset does not come with an official train/test split, so we simply use 10% of the data as a dev set. The original paper reported results for 10-fold cross-validation on the data.

1 Activation

Replace the tanh non-linearity by a rectified linear (RELU) unit [2], where RELU(x) = max(0,x). When you train these models, it might help to change the initialization [3]. Make sure that you choose the learning rate carefully. If it is too small, training will be slow whereas if it is too big, you will not learn anything useful.

2 Regularization

You will now implement Dropout [5, 7], a regularizer that has been applied with great success on multiple tasks, including object recognition [6] and language modeling [8]. During training, drop each hidden layer unit with a probability of 1/2. In general, the units you remove will be different for every training sample, although you may also use a single mask for every mini-batch [4]. When testing your model, you should use all hidden units, but multiply the outgoing weights by 1/2 to account for this change.

3 Depth

Finally, try to adjust the number of convnet layers. Depth allows you to learn multiple levels of representation. Play with the architecture of your network (depth, width, filter size, activation, regularization) to see what works best.

4 Write-up

You should write a short report ($\sim$ 2 pages) describing your experiments and results. Also try to analyze the behavior of your systems. Which changes were the most effective? How would you further improve your models?

Please hand in your report before or at the beginning of the lab session on Wednesday, September 28. You should also submit your code. Please submit your writeup and code to *dl4nlp2016@gmail.com*.
